T Test Problems And Solutions

Following a ten day recovery period, rats (kept at 80 percent body weight) are tested for the number of chocolate chips consumed during a 10 minute period of time both with and without electrical stimulation. The testing conditions are counter balanced. Compute the appropriate t-test for the data provided below.

Solutions to T Test Problems Problem #1. You'll run a t test for independent samples. It doesn't matter that the number of animals in each data set is the same, nor that they are all the same type of animal. You sampled 12 treated individuals and 12 different untreated individuals.

The numerator of the t formula is 4. The denominator is 2.34. The overall t value is 1.71. The critical value at $df = 28$ is 2.048 so that this outcome is not statistically significant. 4. This last problem is a t test for matched samples. In order to solve this you must first find D - the difference between the control subject and the ...

Finally, compute the value of the t statistic: Conduct hypothesis test. Our t test will have df equal to the total of our sample sizes minus 2. In our case, we have 10 participants in each group, so we would have $df = n_1 + n_2 - 2 = 10 + 10 - 2 = 18$. Alpha was set at .05 and we will conduct a two-tailed test.

In reality, the data barely have equal mean, and it leads to incorrect results for the t-test. One solution to relax the equal variance assumption is to use the Welch's test. R assumes the two variances are not equal by default. In your dataset, both vectors have the same variance, you can set `var.equal= TRUE`.

Paired T-Test Definition. The paired t-test gives a hypothesis examination of the difference between population means for a set of random samples whose variations are almost normally distributed. Subjects are often tested in a before-after situation or with subjects as alike as possible. The paired t-test is a test that the differences between the two observations are zero.

0 is negative and positive for a two-tailed test This is a left-tailed test, so $t_0 = 1.771$. ii)Find the t-score for the sample $t = \frac{\bar{x} - \mu}{s/\sqrt{n}} = \frac{19.850 - 20.500}{1.084/\sqrt{14}} = -2.244$ Step 6: The rejection region is drawn based on the critical value t_0 . If the calculated t is in the rejection region (draw a picture), make the decision to reject H_0 ...

The t test returned a p value of 0.33. What is your conclusion regarding the original hypothesis? Would you be correct in stating that the result is significant or insignificant? Problem #9. In problem #4, average superoxide dismutase activity was 30% lower after 10 days than it was in the beginning. The t test gave a p value of 0.07.

t-test - Statistics Solutions

The one sample t-test is a statistical procedure used to determine whether a sample of observations could have been generated by a process with a specific mean. Suppose you are interested in determining whether an assembly line produces laptop computers that weigh five pounds. To test this hypothesis, you could collect a sample of laptop computers from the assembly line, measure their weights ...

Student's t-test deals with the problems associated with inference based on "small" samples: the calculated mean (\bar{X} avg) and standard deviation (s) may by chance deviate from the "real" mean and standard deviation (i.e., what you'd measure if you had many more data items: a "large" sample).

Student's t-Tests

And so as you can imagine, here in this example we are dealing with a paired T test. We aren't looking at two independent groups or two independent samples like you would with the two-sample T test. And so we run a paired T test and the manager wants to test if their times when wearing Harpo's are significantly lower than their times when wearing Zeppo's.
